

CROSS POLLINATION

Newsletter of the Halton Master Gardeners

September Garden To Do List

- ❑ **Perennials** – Divide or transplant spring and summer flowering perennials such as iris, peony, phlox, wood poppy, native anemone as the weather cools. Water the new divisions well. Fill gaps in borders with asters, ornamental cabbage, sedum and mums to extend the colour to the end of the season. Leave some goldenrod for pollinators!
- ❑ **Lawn & Weeds**– Choose a rainy day to overseed lawn, then cover seeds with a [top dressing](#) of fine compost or manure-half the height of the blades of grass should still be visible. Fall feeding increases root growth for an early spring green up. Pull, rake or cut off weeds at ground level. Keep pulling bindweed to reduce the seed bank in soil. Tired of your patchy brown lawn? Consider an alternative like ecolawn which requires less water, mowing and feeding. Info including how to convert a traditional lawn [here](#).
- ❑ **Feed the Soil** - [Add compost or manure](#) to garden beds & lawn.
- ❑ **Bulbs** – Plant spring flowering bulbs such as crocus, tulip, hyacinth now, until before freeze up of soil. Water bulbs after planting. Avoid invasive bulbs such as [scilla](#). Consider planting native & endangered [wood poppies](#) instead of daffodils in a shady location-same yellow colour but no dying bulb foliage to deal with!
- ❑ **Leaves** –Attach the grass catcher bag to the mower and collect a ready supply of chopped leaves to layer into the compost pile or use as mulch on the veggie or flower garden.
- ❑ **Roses** - Stop pruning roses to avoid formation of weaker stems which won't survive the winter.
- ❑ **Veggies** – Green tomatoes-harvest to ripen indoors, freeze or use in recipes. Salad Garden - sow seeds to grow lettuce, spinach, arugula and radishes. Mix and sow seed of different varieties into veggie garden, flower bed or pots. Plant [cover crops](#) such as [red clover](#) & [winter rye](#) on bare soil.
- ❑ **Trees** - Plant new trees and shrubs now to allow them at least six weeks before frost to form roots. Water trees until freeze up, especially ones that were planted this year. Stop feeding and fertilizing shrubs and trees to encourage stems to harden off.
- ❑ **Collect** seed to start new plants and herbs for drying.
- ❑ **Houseplants** - Check houseplants for pests, then start to move indoors gradually when nights get cool. Prune tropicals such as hibiscus and move them into some shade to help transition indoors for the winter, where the light levels are lower.
- ❑ See our [August newsletter](#) for any garden jobs that you may have missed!

CROSS POLLINATION

Spotlight on Beneficial Insects:
Create the right habitat & They Will Come!

Hariette Henry - Halton Master Gardener

Spiders belong to the order **ARANEAE**.

Spiders have eight legs, two main body parts (the abdomen and the cephalothorax), four pairs of eyes (95% of species), no antennae and no wings. They are not insects...even though they are often thought to be. Insects by contrast have six legs, three main body parts (head, thorax and abdomen), two antennae and most species have wings at some point in their lives.

Images: Royal Ontario
Museum, Spiders in Our
Backyard Exhibit

All spiders produce silk but not all spiders use silk to spin webs. Silk is not only used for constructing webs, it is also used for lining burrows, encasing egg sacs and most interestingly to construct safety draglines to prevent themselves from falling off their perches.

All spiders have chelicerae - (mouthparts that include fangs) from which they produce venom. Not all species are harmful to humans and most do not inflict painful or harmful bites.

Beneficial Insects - continued

Spiders prey on insects and other spiders by trapping them in a web or by pouncing on them. The first group, the web builders have the ability to detect their prey through a combination of visual and vibrational cues. They lie in wait until their prey become ensnared in their webs and then the prey are consumed after liquifaction with digestive enzymes. The second group are known as cursorial spiders, or wandering and hunting spiders and they use the same cues to stalk and spot their prey. This group are very valuable to gardeners and farmers as they are highly mobile and can travel to find prey. Some members of this group though, such as crab spiders lie in wait in a single flower in hopes of capturing an unfortunate pollinator.

This crab spider has been able to catch the unfortunate bee by transforming its colours to match its surroundings.

CROSS POLLINATION

Beneficial Insects - Create the Right Habitat & They Will Come!

Spiders are extremely valuable to the farm and garden. Studies have shown that they consume many herbivorous agricultural pests such as insect eggs, beetles, aphids, cutworms, fire ants, spider mites, squash bugs, budworms, caterpillars and asparagus beetles.

In the garden they help to control flies, mosquitoes, moths, beetles, wasps and other pests. Because adult spiders often overwinter in your garden they can start doing their job early in the gardening season.

How to make your property hospitable to spiders and so that they may do their job?

- Number one would be to leave their webs intact as much as possible
- Add tall plants such as sunflowers, cornstalks, and the like, on which to attach their webs, would be useful
- Create spider habitat by adding a loose layer of mulch such as grass clippings and/or dead leaves between the plants and rows in your vegetable garden to shelter these tiny creatures from dry air and sunlight
- Let some native plants grow among the taller plants in the vegetable garden will provide shade and protection
- Leave a planting pot on its side in the garden to create a sheltered micro-habitat for spiders to build webs and trap any unsuspecting meal
- Adopt a no-till approach to the garden to avoid disturbing the hunting ground of spiders
- Provide flowers for crab spiders to trap their prey
- Leave plant stalks standing in winter and not clearing away plant debris until spring
- And finally avoid the use of pesticides and let spiders and other beneficials take care of the pest control for you

Did you Know?

"Hummingbirds use **spider webs** as a source of **spider's** silk in nest construction, being necessary to bind the nest to the tree branch or other substrate and to hold the nest together. Even so, the **hummingbird** must be careful when removing the pieces of webbing, for it may become entangled and be trapped there."

Land of the Silver (White! Yellow! Gray!) Birch

Allyn Walsh – Halton Master Gardener

Who doesn't love seeing a silver birch whether in a cultivated garden or in a wild area? And who remembers wanting to write letters to friends on the lovely bark – and being warned not to! But despite the campfire song, it is quite possible that the tree we are thinking of is one of our native birches (e.g. *Betula papyrifera*) and not the European and Asian birch (*Betula pendula*). There are a number of beautiful native birch trees and they deserve a closer look as they are considered “keystone” plants for wildlife – providing food and shelter for insects, birds and other larger creatures.

Betula papyrifera – white birch

The white birch has a range which covers all of Canada except the far north. Famous for its smooth peeling white bark, it can grow between 20 and 25 metres tall. The leaves are oval or triangular and 5-10 cm long. While white birch is tolerant of a variety of soils, it demands full sun to thrive. Like all birch, both male and female flowers are in the form of catkins, with winged seeds. This relatively short lived tree survives longer in colder climate zones.

White birch images from the [Ontario Tree Atlas](#)

Betula alleghaniensis (yellow birch)

The yellow birch is the largest of Ontario's native birch, slowly growing up to 25 metres tall. Preferring moist rich soil and not too much sun, it does well in wooded areas where it can live 150 years. Its common name comes from the distinctive peeling bark with its definite yellow cast. The relatively long (8-11 cm) leaves are oval with a pointed tip and are finely serrated, alternate on the stem. Male & female catkins appear on the same plant. The fruit in the form of a winged samara is dispersed in fall.

CROSS POLLINATION

Land of the Silver (White! Yellow! Gray!) Birch continued

Betula lenta (cherry birch)

The cherry birch is listed as endangered both federally and provincially and in Ontario is now found only in a small area near St. Catharines. With leaves similar to the yellow birch, its bark is red-black in colour and does not peel. The buds and twigs smell of wintergreen when rubbed. If seen, report it to [Ontario Species at Risk](#)

Cherry birch mages from [Ontario Tree Atlas](#)

Less common native birches:

Betula populifolia (gray birch) and Betula pumila (bog birch)

The gray birch has been gradually moving from the maritime provinces taking over abandoned land. It is now found at the eastern most reaches of Ontario.

The bog or swamp birch is a shrub with rounded leaves not surprisingly found in wet areas.

CROSS POLLINATION

Question of the Month - "Urgent Help Needed"

I have many, many bald faced hornets, paper wasps and yellow jackets - not to mention loads more flying insects on the Magnolia tree by my front door. Our dog stepped on one too! What is going on with my tree? See those white bumps? As well, the hostas below the tree covered in a black tar like substance. I'm very worried. Help me. Thanks. "T. M.

Magnolia Scale: Photo T. Keenan

Hose your magnolias down to try and wash away the honeydew that is attracting the wasps. Magnolia scale (*Neolecanium cornuparvum*) are insects with sucking mouthparts. They can remove large quantities of sap from twigs and young branches. It also produces honeydew which attracts ants (that protect it) and [sooty mould](#).

Cultural controls

Scale thrives on stressed plants, so keep your plant watered and provide proper fertilization-over-fertilization encourages scale. Prune out heavily infested branches. Attract natural predators of soft scale such as [predatory beetles](#) (e.g. families Coccinellidae and Anthribidae), and [parasitic wasps](#) primarily in the hymenopteran families Encyrtidae and Eulophidae. Encourage a healthy ecosystem in your yard.

Physical control.

Because of their large size, female scales can be removed by hand. It is best to do this in July before crawlers emerge. Wear rubber gloves and rub off with the use of a scrubbing brush, but do not scrub hard enough to injure the bark.

Chemical control.

Horticultural oils, often called summer oils, kill by suffocation. These can be applied after the crawlers have emerged in late August and can be very effective in reducing the scale population. Be sure to obtain good coverage. Heavier dormant oils can also be applied in late fall before freezing weather and again in early spring before the flower buds swell to kill the overwintering nymphs located on the stems. Do not exceed the label rate, which is usually a 2 percent concentration of oil in the spray that is applied. Always follow label directions.

Insecticidal soaps are long chain fatty acids that kill susceptible insects through direct contact. They are only effective during the crawler stage and require direct coverage to be effective. For a big job - get help. Contact a professional landscaper or arborist, if you have a large tree and heavy infestation.
